

Love AI More. Trust AI Less.

DSCT lecture walkthrough

1 The call

Claim: Increasing simultaneous requests should increase throughput until parallelism is saturated. The evidence and overlap check support this conditionally: “bigger GPU = faster” does not hold as a universal explanation; actual parallelism and memory placement matter. **Confidence decision:** medium-high for these measured settings, not a universal law.

2 Instructor notes

Say: “An AI could narrate the curve beautifully and still be wrong about what was measured.” Ask students to point to the claim, evidence, assumption, check, and confidence sentence before discussing causes.

3 Student activity (5 minutes)

In pairs, choose one series. Write (1) a one-sentence claim, (2) two numbers as evidence, (3) one assumption, and (4) a check using the overlap ratio. Then mark the claim supported, refuted, or undecidable.

4 Reflection

What would you measure next to distinguish “the GPU is saturated” from “the benchmark’s setup overhead is hidden”? Why would that measurement change your confidence?
